

## ER Diagram

- Many to Many

A can have multiple B and B can have multiple A

- One to Many

A can have multiple B but B can only have one A

- One to One

A can have only one B and B can have only one A

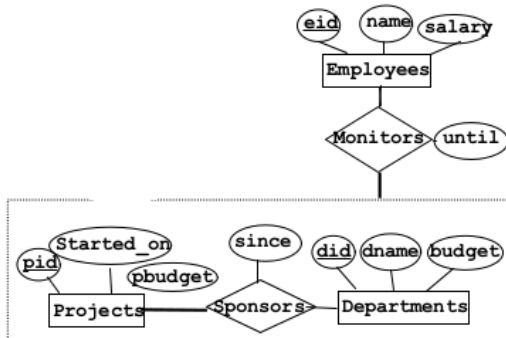

- At least one

Bold arrow specify there is at least one element.

	A have at least one
	A have exactly one

- Aggregation

Allows us to treat a relationship set R as an entity set so that R can participate in other relationships

## Relational algebra

Selection	$\sigma_{condition}(Element)$
Projection	$\pi_{attributes}(Element)$
Renaming	$\rho(R(A_1, \dots, A_n), R_{alias}(B_1, \dots, B_n))$
Cross product	$\times$
Join	$\bowtie$
Division	$\div$
Intersection	$\cap$
Union	$\cup$
Set different	$-$

- Condition/Theta Join  $R_{out} = R_{in1} \bowtie_{condition} R_{in2} = \sigma_{condition}(R_{in1} \times R_{in2})$
- Equi Join:  $R_{out} = R_{in1} \bowtie_{R_{in1}.a_1 = R_{in2}.b_1, \dots, R_{in1}.a_n = R_{in2}.b_n} R_{in2}$  Condition join where condition contains ONLY equalities
- Natural Join: Equijoin on all common attribute

## Sql

### Datatype

Char(n)	A character string of fixed length n
---------	--------------------------------------

VarChar(n)	Denotes a string of up to n charaters
INT or INTEGER	An integer
SHORTINT	Smaller integer
FLOAT or REAL	Float number
DOUBLE PRECISION	Double
DATE	Date format YYYY-MM-DD
TIME	Time format: hh:mm:ss

#### Table operations

```
--Create table
CREATE TABLE Students
(
    id INT NOT NULL,
    name VARCHAR(20),
    login CHAR(10),
    major VARCHAR(20) DEFAULT 'undefined',
    school_id INT,
    PRIMARY KEY(id),
    FOREIGN KEY(school_id) REFERENCES School(id)
)

--Drop table
DROP TABLE Students

--Alter table
ALTER TABLE Students ADD COLUMN firstyear:integer
```

#### Row operation

```
--INSERT
INSERT INTO Students (id, name, faculty) VALUES (8908998, 'Dupont', 'Science')

--Delete
DELETE FROM Students WHERE id = 0894984

--Update
UPDATE Students SET faculty = 'Arts' WHERE id = 9849849
```

#### Trigger

```
CREATE TRIGGER updateSkater
    AFTER DELETE ON Skaters
    REFERENCING OLD TABLE AS DeletedSkaters
    FOR EACH STATEMENT
    INSERT
    INTO StatisticsTable(ModTable, ModType, Count)
    SELECT 'Skaters', 'delete', COUNT(*)
    FROM DeletedSkaters

Use begin/end to encapsulate more than one
action
FOR EACH ROW/STATEMENT
WHEN ...
BEGIN ATOMIC
    do 1thing;
    do 2nd thing;
END
```

#### XML

]>

```

Data types: PCDATA (parsed character data) or CDATA (unparsed)

### Attributes

- ID unique identifier (similar to primary key)
- IDREF: reference to single ID
- IDREFS: space-separated list of references

### Values

- can give a default value
- #REQUIRED must exist
- #IMPLIED optional

Specified in an XML file with <!DOCTYPE name SYSTEM "path/to/thing.dtd">

Can use regex style things too. \* is 0 or more. + is 1 or more, (a | b)? is one or the other

## XPATH

- /bibliography/book/author all author elements by root navigating through those elements
- /bibliography/book/@ISBN All ISBN attributes
- //title all title elements anywhere in the document
- /bibliography/\*/title titles of bibliography entries assuming that there could be books, journals, reports, etc...
- /bibliography/book[@year>1995] returns books where the year > 1995
- /bibliography/book[author='FooBar']/@Year returns the years of books written by FooBar
- /bibliography/book[count(author) <2]
- /bibliography/book/author[position()=1]/name position is the location of the node in the node set

## XQuery

For	Let
for \$b in document("bib.xml")/bib/book return <result> \$b</result>	let \$b in document("bib.xml")/bib/book return <result> \$b</result>
<result><book>...</book></result> <result><book>...</book></result> <result><book>...</book></result> ... <result><book>...</book></result>	<result> <book>...</book> <book>...</book> .. <book>...</book> </result>

<p>-Basic Queries: '/' to navigate one path at a time Example:/Bookstore/Book/Title  '/' all paths following this Example://Title When wanting to access an attribute of an element use @ Example:/Bookstore/Book/data(@ISBN) ' ' OR operator ONLY USED INSIDE CONDITIONS Example:/Bookstore/Book Magazine/Title '=' can act like == like in Self-Join Queries below Navigation accesses: Example: parent::* *::child following-silbling::*</p> <p><b><u>-Queries involving CONDITIONS</u></b> <b><u>1condition:</u></b> Example:/Bookstore/Book[@Price&lt;30] Example:/Bookstore/Book/Authors/Author[2] the 2nd author of each element</p> <p><b><u>2conditions:</u></b> To write a condition, it needs to be inside '['...]' then followed by the output that we are looking for Example:/Bookstore/Book[@Price&lt;30]/Title <b><u>Condition to find elements that contain other elements:</u></b> Example:/Bookstore/Book[Remark]/Title <b><u>Conditions &amp;&amp; Conditions + Some output:</u></b> Example: Looking for a title that has one last name =Ullman and price&lt;90 /Bookstore/Book[@Price&lt;90 and Authors/Author/Last_Name="Ullman"]/Title <b><u>Conditions Inside Conditions + Some output:</u></b> Example:Looking for a title with author ="Jeffrey Ullman" and price&lt;90 /Bookstore/Book[@Price&lt;90 and Authors/Author/[Last_Name="Ullman" and First_Name="Jeffrey"]]/Title <b><u>Conditions &amp;&amp; !Conditions + Some output:</u></b> Example:Looking for a title with author ="Ullman" and NOT author="Widom" /Bookstore/Book[/Authors/Author/Last_Name="Ullman" and count(/Authors/Last_Name="Widom"=0)]/Title <b><u>The condition 'contains':</u></b> /Bookstore/Book[contains(Remark, "great")]/Title</p>	<p><b><u>Self-Join Query</u></b> Querying two instances of the database at one and joining them together.Trying to find the magazines wheres theres a book with the same title. Example: doc("BookstoreQ.xml")/Bookstore/Magazine[Title=doc("BookstoreQ.xml")/Bookstore/Book/Title]</p> <p><b><u>Navigation Accesses</u></b> The name() function returns the name of a tag or element To find all elements whose parent is not "Bookstore" or "Book" <b><u>/Bookstore/*[name(parent::*)!="Bookstore" and name(parent::*)!="Book"]</u></b></p>
--	---

- **Record id (rid)** = internal identifier of a record:   
 <page id, slot #>.
- Can move records on page without changing rid;

--	--	---

Indexing

COST MODEL	HEAP FILES	SORTED FILES
<p>Measure performances by simplifying the parameters (10 focused):</p> <ul style="list-style-type: none"> <li>☆ only consider disk reads (ignore writes)</li> <li>☆ only consider number of I/Os and not the individual time for each</li> </ul>	<ul style="list-style-type: none"> <li>☆ Linked, unordered list of all pages of the file</li> <li>☆ Is it good for: <ul style="list-style-type: none"> <li>● scan retrieving all records (SELECT *)?</li> <li>▲ yes, you have to retrieve all</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>☆ Records are ordered according to one or more attributes of the relation</li> <li>☆ Is it good for: <ul style="list-style-type: none"> <li>● scan retrieving all records (SELECT *)?</li> </ul> </li> </ul>

read (ignores page pre-fetch) ☆ Average-case analysis: based on several simplistic assumptions. ● delete/update  ▲ depends on where	pages anyway ● equality search on primary key ▲ not great: have to read on avg half the pages for 1 record ● range search or equality search on non-primary key ▲ not great, all pages need to be read ● insert ▲ yes, can insert anywhere ● delete/update ▲ depends on where	▲ yes, you have to retrieve all pages anyway ● equality search on sort attribute ▲ good: find first qualifying page with binary search (log2) ● range search on sort attribute ▲ good: find first qualifying page with binary search (log2): adjacent pages might have additional matching records
---	---	--

Let suppose we have a relation R (A, B, C, D, F) such that:

- A and B are int (6 byte)
- C-F are char [40] (10 byte per char).
- Tuple = 172 bytes. 200,000 tuples
- Each data page has 4000 bytes and is around 80% full
- B values are uniformly distributed
- Rid = 10 bytes
- Size of pointer in intermediate page = 8 bytes
- Index pages are 4K and between 50%-100% full

Goal	Formula	With this example
Number of pages	$\frac{\text{number of tuples} * \text{tuple size}}{\text{fill rate} * \text{page size}}$	$\frac{172 * 200000}{40000 * 0.80} = 10750$
Index entry size in root and intermediate pages	$\text{size of key} + \text{size of pointer}$	$6 + 8 = 14 \text{ bytes}$
Average number of rids per data entry	$\frac{\text{number of tuples}}{\text{different values (if uniform)}}$	$\frac{200,000}{20,000} = 10$
Average length per data entry	$\text{size of key} + (\text{number of rids} * \text{size of rid})$	$6 + 10 * 10 = 106$
Average number of data entries per leaf page	$\frac{\text{fillrate} * \text{page size}}{\text{length of data entry}}$	$\frac{0.75 * 4000}{106} = 28 \text{ entries per page}$
Estimate number of leaf page	$\frac{\text{number of different values}}{\text{number of entrier per page}}$	$\frac{20,000}{28} = 715$
Number of entries in intermediate pages	$\frac{\text{fillrate} * \text{page size}}{\text{lenght of index enty}}$	$\min = \frac{0.5 * 4000}{14} = 143, \max = \frac{1 * 4000}{14} = 285$
Height of tree	$(\text{nb of entry in intermediate page})^{h-1} > \text{nb of leaf page}$	3

Non-clustered index B-tree with <k, list of rid>

Height of tree = Number of leaf pages / (min | max)? number of entries in intermediate pages

Give the pids of all projects within department D2 that started in 2014.

At the top, it shows the sequence: Map tasks → Sort, group Shuffle → Reduce tasks. Below this, a detailed view of the Shuffle phase is shown. It depicts a 'Distributed File System' (DFS) with multiple nodes. Map tasks (yellow squares) write their outputs to the DFS. Reduce tasks (yellow squares) then read from the DFS. The 'Group and Shuffle' process is shown as a complex network of connections between the map outputs and the reduce inputs, representing the distribution of data based on keys. Labels include 'DFS', 'Map', 'Reduce', 'Group and Shuffle', and 'Distributed File System'.</p>

## Map reduce

**Nested loop joins:**

- Simple nested loop join: For each tuple in the outer relation P, we scan the entire inner relation S
  - $cost = PartPages + CARD(P) * SkaterPages = 1000 + 100000 * 500$
- Page-oriented Nested Loops join: For each page of P, get each page of S, and write out matching pairs of tuples <p, s>, where p is in P-page and s is in S-page.
  - $cost = PartPage + PartPage * SkaterPage = 1000 + 1000 * 500$

**Join cost on relation R1(outer) and R2(inner):****Block oriented nested loop join:**

- Smaller relation fits in main memory+2extra buffer page:
$$cost = page(R1) + page(R2)$$
- No relation fits in main memory(B join frame):
$$cost = page(R1) + \frac{page(R2) * page(R1)}{B - 2}$$

**Index nested loop join**

- Index on the join column of one of the relation(R2):
$$cost = page(R1) + card(R1) * cost\_finding\_index(R2)$$
- If the join attribute is primary key in inner relation

**Sort merge join**

- Sort P and S on the join column, then scan them to do a "merge" (on join col.), and output result tuples
  - Advance scan of P until current P-tuple >= current S tuple, then advance scan of S until current S-tuple >= current P tuple; do this until current P tuple = current S tuple.
  - At this point, all P tuples with same value in Pi (current P group) and all S tuples with same value in Sj (current S group) match; output <p, s> for all pairs of such tuple 1s.
- P is scanned once; each S group is scanned once per matching P tuple. (Multiple scans of an S group are likely to find needed pages in buffer.)
