ER Diagram

Many to Many

A can have multiple B and B can have multiple A

One to Many

A can have multiple B but B can only have one A

One to One

A can have only one B and B can have only one B

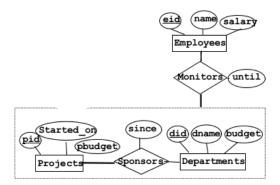

• At least one

Bold arrow specify there is at least one element.

A R	A have at least one
$A \longrightarrow R$	A have exactly one

Aggregation

Allows us to treat a reltionship set R as an entity set so that R can participate in other relationships

Relational algebra

Selection	$\sigma_{condition}(Element)$
Projection	$\pi_{attributes}(Element)$
Renaming	$\rho(R(A_1,,A_n),R_{alias}(B_1,,B_n)$
Cross product	×
Join	×
Division	
Intersection	Λ
Union	U
Set different	_

- Condition/Theta Join $Rout = Rin1 \bowtie cRin2 = \sigma c(Rin1 \times Rin2)$
- Equi Join: $Rout = Rin1 \bowtie Rin1a1 = Rin2b1, ..., Rin1an = Rin2bnR$ in2 Condition join where condition contains ONLY equalities
- Natural Join: Equijoin on all common attribute

Sql

Datatype

Char(n) A character string of fixed length n
--

VarChar(n)	Denotes a string of up to n charaters
INT or INTEGER	An integer
SHORTINT	Smaller integer
FLOAT or REAL	Float number
DOUBLE PRECISION	Double
DATE	Date format YYYY-MM-DD
TIME	Time format: hh:mm:ss

Table operations

```
--Create table
CREATE TABLE Students
(

id INT NOT NULL,

name VARCHAR(20),

login CHAR(10),

major VARCHAR(20) DEFAULT 'undefined',

school_id INT,

PRIMARY KEY(id),

FOREIGN KEY(school_id) REFERENCES School(id)
)

--Drop table
DROP TABLE Students

--Alter table
ALTER TABLE Students ADD COLUMN firstyear:integer
```

Row operation

```
--INSERT
INSERT INTO Students (id, name, faculty) VALUES (8908998, 'Dupont', 'Science')
--Delete
DELETE FROM Students WHERE id = 0894984
--Update
UPDATE Students SET faculty = 'Arts' WHERE id = 9849849
```

Trigge

```
CREATE TRIGGER updateSkater
AFTER DELETE ON Skaters
REFERENCING OLD TABLE AS DeletedSkaters
FOR EACH STATEMENT
INSERT
INTO StatisticsTable (ModTable, ModType, Count)
SELECT 'Skaters', 'delete', COUNT(*)
FROM DeletedSkaters
Use begin/end to encapsulate more than one
action
FOR EACH ROW/STATEMENT
WHEN ...
BEGIN ATOMIC
do 1thing;
do 2nd thing;
END
```

Data types: PCDATA (parsed character data) or CDATA (unparsed)

Attributes

- ID unique identifier (similar to primary key)
- IDREF: reference to single ID
- IDREFS: space-seperated list of references

Values

- can give a default value
- #REQUIRED must exist
- #IMPLIED optional

Specified in an XML file with <!DOCTYPE name SYSTEM "path/to/thing.dtd">

Can use regex style things too. * is 0 or more. + is 1 or more, (a | b)? is one or the other

XPATH

- /bibliography/book/author all author elements by root navigating through those elements
- /bibliography/book/@ISBN All ISBN attributes
- //title all title elements anywhere in the document
- /bibliography/*/title titles of bibliography entries assuming that there could be books, journals, reports, etc...
- /bibliography/book[@year>1995] returns books where the year > 1995
- /bibliography/book[author='FooBar']/@Year returns the years of books written by FooBar
- /bibliography/book[count(author) <2]
- /bibliography/book/author[position()=1]/name position is the location of the node in the node set

XQuery

For	Let					
for \$b in document("bib.xml")/bib/book	let \$b in document("bib.xml")/bib/book					
return <result> \$b</result>	return <result> \$b</result>					
<result><book></book></result>	<result></result>					
<result><book></book></result>	<book></book>					
<result><book></book></result>	<book></book>					
	••					
<result><book></book></result>	<book></book>					

-Basic Queries: '/' to navigate one path at a time **Self-Join Query** Example:/Bookstore/Book/Title all paths following this Example://Title When wanting to access an attribute of an element use @ **Navigation Accesses** Example:/Bookstore/Book/data(@ISBN) '|' OR operator ONLY USED INSIDE CONDITIONS Example:/Bookstore/Book|Magazine/Title can act like = like in Self-Join Queries below Navigation accesses: Example: parent::* *::child following-silbling::* -Queries involving CONDITIONS 1condition: Example:/Bookstore/Book[@Price<30] Example:/Bookstore/Book/Authors/Author[2] the 2nd author of each element **2conditions:** To write a condition, it needs to be inside '[...]' then followed by the output that we are looking for Example:/Bookstore/Book[@Price<30]/Title **Condition to find elements that contain other elements:** Example:/Bookstore/Book[Remark]/Title **Conditions && Conditions + Some output:** Example: Looking for a title that has one last name =Ullman and price<90 /Bookstore/Book[@Price<90 and Authors/Author/Last Name="Ullman"]/Title Conditions Inside Conditions + Some output:

Quering two instances of the database at one and joining them together. Trying to find the

magazines wheres theres a book with the same title. Example:

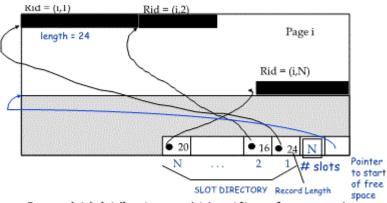

doc("BookstoreQ.xml")/Bookstore/Magazine[Title=doc("BookstoreQ.xml")/Bookstore/Book/Title]

The name() function returns the name of a tag or element

To find all elements whose parent is not "Bookstore" or "Book"

/Bookstore/*[name(parent::*)!="Bookstore" and name(parent::*)!="Book"]

Example:Looking for a title with author ="Jeffrey Ullman" and price<90 /Bookstore/Book[@Price<90 and Authors/Author/[Last Name="Ullman" and First Name="Jeffrey"]]/Title Conditions && !Conditions + Some output: Example:Looking for a title with author ="Ullman" and NOT author="Widom" /Bookstore/Book[/Authors/Author/Last Name="Ullman" and count(/Authors/Last_Name="Widom"=0]/Title The condtion 'contains': /Bookstore/Book[contains(Remark, "great")]/Title

Buffer

DBMS stores information persistently	When loading a page from disk:	If requested is not in pool:			
on ("hard") disks.	☆ Replacement frame must have	☆ If there is an empty frame, use			
☐ Unit of transfer main-	"pin counter" of O	it			
memory/disk: disk blocks or pages.	☐ When requesting a page that is in	☆ Else choose an empty frame for			
☐ Timing:	the buffer	replacement. If the frame is dirty			
☆ 2- 20 msec for random data	☆ Increment pin counter	(page was modified), write it to			
block (bad seek time)	☐ After operation has finished	disk			
☆ If blocks are sequentially on	☆ Decrement pin counter	☆ Read requested page into chosen frame			
disk, only +1ms per block	☆ Set dirty bit if page has been	Buffer management in DBMS requires			
☆ Compare main memory access: in	modified:	ability to:			
nanoseconds	☐ Frame is chosen for replacement	☆ pin a page in buffer pool, force			
☐ Basic operations (READ/WRITE	by a replacement policy:	a page to disk (important for			
from/to disk)	☆ Only unpinned page can be	implementing CC & recovery),			
☐ Why disks?	chosen (pin count = 0)	☆ adjust replacement policy, and			
☆ Cheaper than Main Memory	☆ Least-recently-used (LRU), Clock, MRU	pre-fetch pages based on			
☆ Higher Capacity	etc.	access patterns in typical DB			
☆ Main Memory is volatile		operations.			

Indexing		
COST MODEL	HEAP FILES	SORTED FILES
Measure performances by simplifying	☆ Linked, unordered list of all	☆ Records are ordered according to
the parameters (IO focused):	pages of the file	one or more attributes of the
☆ only consider disk reads (ignore	☆ Is it good for:	relation
writes)	scan retrieving all records	☆ Is it good for:
$$^{\mbox{\tiny $\!$	(SELECT *)?	scan retrieving all records
not the individual time for each	▲ yes, you have to retrieve all	(SELECT *)?

read (ignores page pre-fetch)	pages anyway	▲ yes, you have to retrieve all				
☆ Average-case analysis; based on	equality search on primary key	pages anyway				
several simplistic assumptions.	▲ not great: have to read on	equality search on sort				
delete/update	avg half the pages for 1 record	attribute				
	 range search or equality search 	▲ good: find first qualifying				
▲ depends on where	on non-primary key	page with binary search (log2)				
	▲ not great, all pages need to	range search on sort attribute				
	be read	▲ good: find first qualifying				
	insert	page with binary search (log2):				
	▲ yes, can insert anywhere	adjacent pages might have				
	delete/update	additional matching records				
	▲ depends on where					

Let suppose we have a relation R (A, B, C, D, F) such that:

- A and B are int (6 byte)
- C-F are char [40] (10 byte per char).
- Tuple = 172 bytes. 200,000 tuples
- Each data page has 4000 bytes and is around 80% full
- B values are uniformly distributed
- Rid = 10 bytes
- Size of pointer in intermediate page = 8 bytes
- Index pages are 4K and between 50%-100% full

Goal	Formula	With this example				
Number of pages	number of tuples * tuple size fill rate * page size	$\frac{172 * 200000}{40000 * 0.80} = 10750$				
Index entry size in root and intermediate pages	size of key + size of pointer	6 + 8 = 14 bytes				
Average number of rids per data entry	number of tuples different values (if uniform)	$\frac{200,000}{20,000} = 10$				
Average length per data entry	size of key + (number of rids * size of rid)	6 + 10 * 10 = 106				
Average number of data entries per leaf page	fillrate * page size length of data entry	$\frac{0.75*4000}{106} = 28 \text{ entries per page}$				
Estimate number of leaf page	number of different values number of entrier per page	$\frac{20,000}{28} = 715$				
Number of entries in intermediate pages	fillrate * page size lenght of index enty	$min = \frac{0.5 * 4000}{14} = 143, \max = \frac{1 * 4000}{14} = 285$				
Height of tree	$(nb\ of\ entry\ in\ intermediate\ page)^{h-1}>nb\ of\ leaf\ page$	3				

Non-clustered index B-tree with <k, list of rid>

Height of tree = Number of leaf pages / (min | max)? number of entries in intermediate pages

Give the pids of all projects within department D2 that started in 2014.

$$\pi_{pid}\left(\sigma_{dep_{id}=D2\land start_{date}=2014}(Project)\right)$$

Give the pids of all projects that have at least one excellent evaluation

$$\pi_{Project.pid}\Big(\sigma_{Evaluation.grade='execlent'}(Project\bowtie Evaluation)\Big)$$

Force Flush strategy All changes are flush to disk BEFORE commit	Completed transaction need not action Active transaction might have partial changes on disk(Need undone)	Append to log file log record before flushing At commit/abort append to log file commit/abort log record When recovering from crash: Scan log backward for each record if commited ignore otherwise install Before-Image of the record
No force flush strategy Changes might be flushed at any time(BEFORE/AFTER commit)	Done transaction might have missing changes (must be redone) Active/Aborted transaction might have been flushed before crash(Must be undone)	 For each write(x) of a transaction T with x being on page P: Log record with before AND after image of x(Before so you can undo changes, After so you can redo changes) Flush before-image to disk before flushing the P Flush after-image to disk before commit of T At commit/abort append commit/abort record to log file and flush

- Unrepeatable read: If T1 read twice the same data item but T2 change its value between the first and the second
- <u>Dirty read:</u> If T2 read from T1 before T1 commit.
- Lost update: If T2 modify a data item modified by T1 without taking in account the value modified by T1.

Schedule

- Serial schedule: All transaction one after the other
- <u>Non-serial schedule:</u> Transaction overlap
- <u>Serializable</u>: Dependency graph has no cycle(T1 always does action before T2)
- Recoverable schedule: If transaction T_i reads a value written by transaction T_i then T_i commit only after T_i committed
- Avoiding cascading aborts: A transaction reads only values written by committed transactions.
- <u>Strict:</u> A transaction only read or overwrite value written by committed transaction

Schedule examples:

Strict and serializable

r1(x), w2(x), c2, w1(x), c1

- Avoids cascading aborts, non-strict, serializable
- Recoverable, not avoiding cascade aborts, serializable

r1(x), w2(y), w2(x), r1(y), c2, c1

• Not recoverable, serializable

r1(x), w2(y), r1(x), c1, c2

• Not recoverable, Not-serializable

Unrecoverable Recoverable		Recoverable		Avoids cascading		Non strict		Strict		Strict and serializable			
		schedul	e with	schedule with									
		cascadir	ng abort	commit									
T1	T2	T1	T2	T1	T2	T1	T2	T1	T2	T1	T2	T1	T2
R(A)		R(A)		R(A)		R(A)		W(A)		W(A)		R(x)	
W(A)		W(A)		W(A)		W(A)			W(A)	abort			W(x)
	R(A)		R(A)		R(A)	abort		abort			W(A)		commit
	commit	abort		commit			R(A)		commit		commit	W(x)	
commit			abort		commit		commit					commit	

Lock request: Lock release: If lock is S, no X lock is active and the request queue is empty: Remove the lock from the granted lock queue If this was the only lock granted on this object: Add the lock to the granted lock queue and set the lock type to S Grant one X lock(If the first of the request is a X lock) If lock is X and no lock active(request queue is also empty): Add the lock to the granted lock queue and set the lock type to X Grant n S lock(If the first n element are S lock) Add the lock to the request lock queue Deadlocks: Solve Deadlock: Make the wait-for graph(T_i need ressource lock by T_i) Add a timeout for each transaction and abort if transaction timeout. If cycle then we have a deadlock (Nooooooooooooo...) Problem on what timeout value to choose Request all the lock at the beginning of the transcation

Pre	edicate locking:	Predicate looking example:					
•	Grant lock on all records that satisfies logical predicates(e.g.	•	Assume 2 tranascrtions:				
	depid>5, age > 2*salary)	-	$UPDATE\ Skaters\ set\ rating\ =\ 7\ WHERE\ sid\ =\ 123$				
•	More bullshit	-	SELECT max(age) FROM Skaters WHERE rating = 5				
		•	Assume: T1 execute first then it has a X-lock on Skaters with				
			sid=123				
		•	Assume: T2 has to scan the entire table to get skater with rating=5				
		-	For each tuple				
			- set S-lock on tuple				
			- Check condition				
			- If condition TRUE keep lock and return value				
			- If condition FALSE release lock				
		-	It need to read the tuple where sid=123 and rating= 5 but block				
			has T1 has a lock on it.				
		-	T2 is block by T1 although there is no conflict				
1							

Problems of strict 2PL locking:

- Very restrictive, low concurrency, problem with long query
- More and more exception

<u>In order to allow for more concurrency, SQL2 defines various levels of isolation</u>

- Assumed to be implemented by different forms of locking
- Avoid different levels of anomalies
- Used for non-critical transactions or read-only transactions
- Lower levels of isolation do NOT provide serializability

Problem

- Definitions are no more appropriate if systems do not use locking but other forms of concurrency control
- For instance, Oracle's "serializable" level does not provide serializable schedule as defined in the literature

Isolation level:

- In principle isolation levels are independent of concurrency control mechanics
- In reality they were defined with locking in mind

Isolation level/Anomaly	Dirty read	Unrepeatable read	Phantom
Read uncommitted	Maybe	Maybe	Maybe
Read committed	No	Maybe	Maybe
Repeated reads	No	No	Maybe
Serializable	No	No	No

Read uncommitted:

- Read op. do not set locks; can read not-committed updates
- Read committed:
- Read op. set short S locks; have to wait for X locks to be released
- release lock immediately after execution of op
- Repeated reads:
- Read operations set standard lock S locks; standard 2PL
- Serializable
- Read op. must set S locks that cover all objects that are read
- predicate locks or coarse locks (e.g., lock on entire relation)

Big data

Some bullshit info:

- Hardware
- CPU does not increase
- Instead muticode
- Usage
- Astronomy: high-resolution, high-frequency sky surveys
- Medicine: digital records, MRI, ultrasound
- Biology: sequencing data
- User behavior data: click streams, search logs

Parallel Query Evaluation:

- Inter-query parallelism
- Different queries run in parallel on different processors; each query is executed sequentially
- Inter-operator parallelism
- Different operator within the same execution tree run on different processors
- Intra-operator parallelism
- A single operator(JOIN, GROUP, ...) runs on many processor

Horizontal data Partitioning:

- Data
- Large table R(K, A, B, C)
- Key value store KV(K, V)
- Goa
- Partition into chunks $c_1, \dots c_n$ of records stored at N nodes
- Range partition
- Equal size of each chunk
- Hash partitioned on attribute X
- Record r goes to chunk i, according to hash function
- xample: hash function H(r.X) mod P+1
- Range partitioned on attribute X
- Partition range of X into: $-\infty = v_0 < v_1 < \dots < v_p = \infty$
- Record r goes to chunk i, if $v_{i-1} < t . X < v_i$

Vertical Partitioning:

- Column stores
- Data: relation R(K, A, B, C)
- Partition into RA(K, A), RB(K, B), RC(K, C)
- Query:
- SELECT A FROM R
- Query only needs to access partition RA
- Much less IO

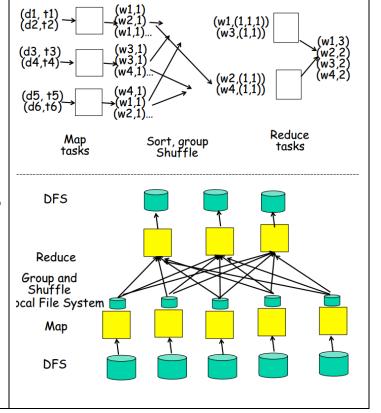

Execution steps:

- User indicates m (number of map tasks), r (number of reduce tasks),
 key/value set = document Set DS
- System creates m map tasks and splits input set of 1key/value pairs into m partitions and gives each map task one partition as input
- Each Map task executes user written map function
- WordCountMap:
- For each input key/value pair (dkey, dtext)

For each word w of dtext

Output key-value pair (w, 1)

- Next step only completes once all map tasks have completed
- System sorts map outputs by key and transforms all key/value pairs
 (k, v1), (k, v2), ... (k, vn) with same key k to one key/value-list pair
 (k, (v1, v2, ... vn))
- For Word count: all ('and', 1), ('and', 1), ('and', 1) ... are transformed into one ('and', (1,1,1,...))
- System partitions output by key into r partitions and assigns these partitions as inputs to the r reduce tasks
- Each reduce task executes user written reduce function
- WordCountReduce:
- For each input key/value-list pair $(k,(v1,v2,\dots\,vn)$ Output (\mathbf{k},\mathbf{n})

Map reduce

Relational Operators with Map/reduce

- Assume R(A, B, C) relation (no duplicates)
- Selection with condition c on R
- for each tuple t of R for which condition c holds, output (t,t)
- Reduce: identity, that is output (t, t)
- Projection on A, B, of R
- <u>Map:</u> transform each tuple t = (a, b, c) of R into tuple t' = (a, b) of R, and output (t', t')
- There might now be duplicates, that is several (t', t') tuples, the group function will aggregate them to (t', (t', ..., t'))
- Reduce: for each tuple (t', (t', ..., t')) output (t', t')
- Natural Join R(A,B,C) with Q(C,D,E) via hash-join(SELECT FROM R1,R2)
- Map

For each tuple (a,b,c) of R, output (c,(R,(a,b)))For each tuple (c,d,e) of Q, output (c,(Q,(d,e)))

- Group and shuffle will aggregate all key/value pairs with same c-value
- Reduce:

for v1 in Rt, for v2 in Qt, output(c,v1,v2)
Basically produces all combinations (c, ai,bi,dj,ej)

Grouping: SELECT a, sum(b) GROUP by (a)

- Map: for each tuple (a, b,c) of R output (a,b)
- Group and shuffle will create for each value a a key/value-list (a, (b1, b2, ...)
- Reduce: for each (a, (b1, b2, ...)) perform aggregation (e. g., b1 + b2, ...)

Pig latin:

- Users = LOAD 'users' AS (name,age);
- Filtered = FILTER Users BY age >= 18 AND age <= 25;

dump results;
```

Query evaluation

5 * #pages

Examples for flowing problems: Reduction factor of a condition defined as **Participates** $Red(\sigma_{condition}(R)) = |\sigma_{condition}(R)|/|R|$ $Red\left(\sigma_{rating=5}(Skaters)\right) = \frac{|\sigma_{rating=5}(Skaters)|}{|Skaters|} = \frac{15}{100} = 0.15$ 100 000 tuples 1000 pages If not known, DBMS makes simple assumptions 100 tuples per page $Red\left(\sigma_{rating=5}(Skaters)\right) = \frac{1}{|diff \ rating|} = 0.1$ $Red\left(\sigma_{age \le 10}(Skaters)\right) = \frac{10 - \min(age)}{\max(age) - \min(age)} = \frac{10 - 4}{30 - 4} = \frac{6}{26} = 0.025$ Skaters 40 000 tuples 500 pages **Result size:** number of input tuples * reduction factor 80 tuples per page How to know the number of different values, max, min, Index on sid has 170 leaf page through indices, heuristics, separate statistics (histograms) Index on names has 300 leaf page Simple selection: **Clustered B+tree** No index: Costs: Search on arbitrary attributes: scan the entire relation #LeafPages + #dataPageToRetreive e.g. cost = page(Skaters)Example 1 Search on primary key attributes: scan on average half of S SELECT * FROM Skaters WHERE name sid = 5 e.g. $cost = \frac{page(Skaters)}{2} = 250$ 1 tuple match $cost = 1 \ leaf \ page + 1 \ data \ page = 2$ Index on selection attribute Example 2 Use index to find qualifying data entries, then retrieve corresponding SELECT * FROM Skaters WHERE name LIKE 'Z%' data records. System estimate the number of matching tuples(Around 100 match on 2 data page as its clustered) cost = 1 leaf page + 2 data page = 3Example 3 SELECT * FROM Skaters WHERE name < 'F%' Assume around 10 000 tuples match(On 125 datapage) cost = 1 leaf page + 125 data pages = 126**Unclustered B+tree Unclustered B+tree with sorting:** Sort matching data entries (rid=pid,slot-id) in leaf-pages by page-id Costs: #dataPageToRetreive = #tuplesOnly fast if the the 75 leaf pages with matching entries fit in main #LeafPages + #dataPageToRetreiveRetrieve each page only once and get all matching tuples SELECT * FROM Skaters WHERE name sid = 5 #data pages = #data pages that have at least one matching tuple; Same worst case is total # of data pages Example 2 Example 1 SELECT * FROM Skaters WHERE name LIKE 'Z%' SELECT * FROM Skaters WHERE name sid = 5 Assume around 100 match on 80 data page but we need to retrieve Same some data page twice Example 2 cost = 1 leaf page + 101 data page = 101SELECT * FROM Skaters WHERE name LIKE 'Z%' Example 3 Assume around 100 match on 80 data page SELECT * FROM Skaters WHERE name < 'F%' cost = 1 leaf page + 80 data page = 81Assume around 10 000 tuples match Example 3 $cost = 75 \ leaf \ page + 10 \ 000 \ data \ pages = 10 \ 001$ SELECT * FROM Skaters WHERE name < 'F%' Assume around 10 000 tuples match(assume thataround 490 data cost = 75 leaf page + 490 data pages = 565Note: sorting expensive if leaf-pages do not fit in main-memory Sort: |Skaters Participates| = |Participates| Sometimes a pass 2 is needed Join attribute is primary key for Skaters Pass 0 created more runs than there are main memory buffers Each Participates tuple matches exactly with one Skaters tuple Therefore Pass 1 produces more than one run $|Skaters \times Participates| = |Participates| * |Skaters|$ Pass 2 takes the runs of Pass 1 and merges them Cross product is always the product of individual relation sizes Cost For other joins more difficult to estimate (Continues in next episode...) SELECT sname, age FROM Skaters ORDER BY age If everything fits into main memory (Only pass 0 needed): Read number of data pages sort and pipeline result into next operator (project) Pass 0 + pass 1 needed Pass 0: read # pages, write # pages (have to write temp. results!) Pass 1: read # pages, sort and pipeline result into next operator 3 * #pages Pass 0 + pass1 + pass2 needed

Nested loop joins:

- Simple nested loop join: For each tuple in the outer relation P, we scan the entire inner relation S
- cost = PartPages + CARD(P) * SkaterPages = 1000 + 100000 * 500
- Page-oriented Nested Loops join: For each page of P, get each page of S, and write out matching pairs of tuples <p, s>, where p is in P-page and s is in S-page.
- cost = PartPage + PartPage * SkaterPage = 1000 + 1000 * 500

Join cost on relation R1(outer) and R2(inner):

Block oriented nested loop join:

• Smaller relation fits in main memory+2extra buffer page:

$$cost = page(R1) + page(R2)$$

No relation fits in main memory(B join frame):

s in main memory(B join frame):

$$cost = page(R1) + \frac{page(R2) * page(R1)}{B - 2}$$

Index nested loop join

• Index on the join column of one of the relation(R2):

$$cost = page(R1) + card(R1) * cost_finding_index(R2)$$

• If the join attribute is primary key in inner relation

Sort merge join

- Sort P and S on the join column, then scan them to do a "merge" (on join col.), and output result tuples
- Advance scan of P until current P-tuple >= current S tuple, then advance scan of S until current S-tuple >= current P tuple; do this until current P tuple = current S tuple.
- At this point, all P tuples with same value in Pi (current P group) and all S tuples with same value in Sj (current S group) match; output <p, s> for all pairs of such tuple 1s.
- P is scanned once; each S group is scanned once per matching P tuple.
 (Multiple scans of an S group are likely to find needed pages in buffer.)
